Lecture 9: Sorting Algorithms

Sorting by Exchange: Shell Sort

- Sorting methods based on comparison:
 - Comparisons and hence movements of data take place between adjacent entries only
 - This leads to a number of redundant comparisons and data movements
 - A mechanism should be followed with which the comparisons can take in long leaps instead of short
 - * Donald L. Shell (1959)
 - Use increments:

$$h_{t}, h_{t-1}, h_{t-2}, ..., h_{1}$$

Shell Sort

- Shell sort, also known as the **diminishing increment sort**, is one of the oldest sorting algorithms
- It improves on insertion sort
- Starts by comparing elements far apart, then elements less far apart, and finally comparing adjacent elements (effectively an insertion sort). By this stage the elements are sufficiently sorted that the running time of the final stage is much closer to O(N) than $O(N^2)$

Shell sort: steps

 \triangleright Let A be a linear array of *n* numbers A [1], A [2], A [3], A [n].

> Step 1:

• The array is divided into k sub-arrays consisting of every kth element. Say k= 5, then five sub-array, each containing one fifth of the elements of the original array

```
Sub array 1 \rightarrow A[0] A[5] A[10]
```

Sub array $2 \rightarrow A[1] A[6] A[11]$

Sub array $3 \rightarrow A[2] A[7] A[12]$

Sub array $4 \rightarrow A[3] A[8] A[13]$

Sub array $5 \rightarrow A[4] A[9] A[14]$

Note: The ith element of the jth sub array is located as A $[(i-1) \times k+j-1]$

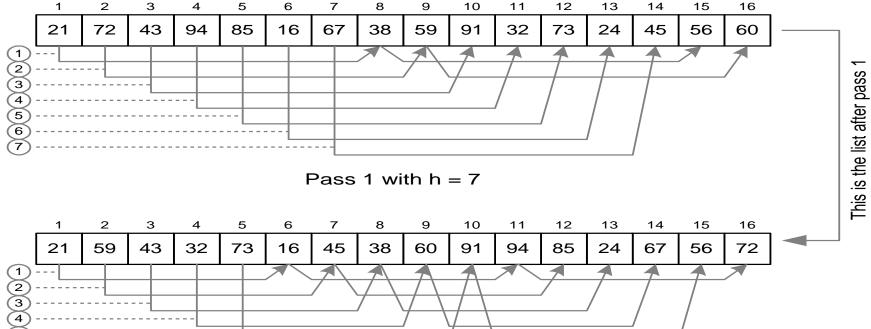

Shell sort: steps

> Step 2:

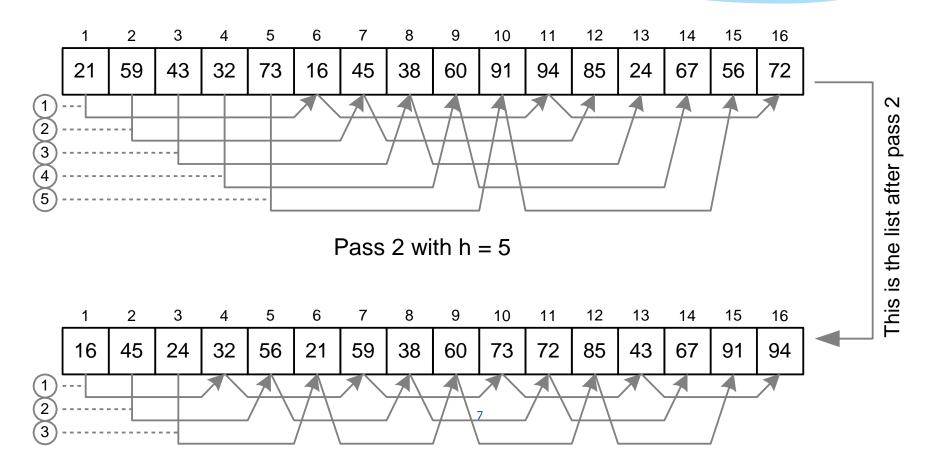

• After the first k sub array are sorted (usually by insertion sort), a new smaller value of k is chosen and the array is again partitioned into a new set of sub arrays

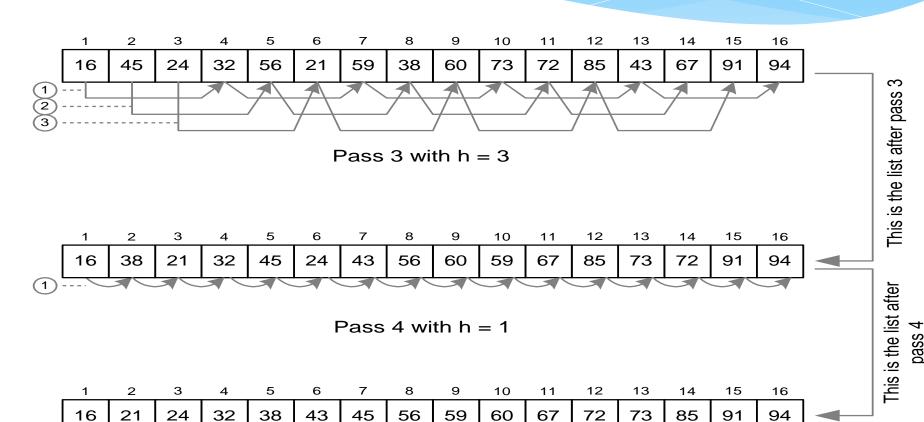

> Step 3:

• Process is repeated with an even smaller value of k, so that A [1], A [2], A [3], A [n] is sorted

Pass 2 with h = 5

Output list

To illustrate the shell sort, consider the following array with 7 elements 42, 33, 23, 74, 44, 67, 49 and the sequence $K=4,\,2,\,1$ is chosen.

Pass = 1 Span = k = 442, 33, 23, 74, 44, 67, 49

Pass = 2 span = k = 2 42, 33, 23, 74, 44, 67, 49

Pass = 3 Span = k = 123, 33, 42, 67, 44, 74, 49

Shell sort: algorithm

- Let A be a linear array of *n* elements, A [1], A [2], A [3], A[*n*] and *Incr* be an array of sequence of span to be incremented in each pass. X is the number of elements in the array *Incr. Span* is to store the span of the array from the array Incr.
- 1. Input *n* numbers of an array A
- 2. Initialise i = 0 and repeat through step 6 if (i < x)
- 3. Span = Incr[i]
- 4. Initialise j = span and repeat through step 6 if (j < n)

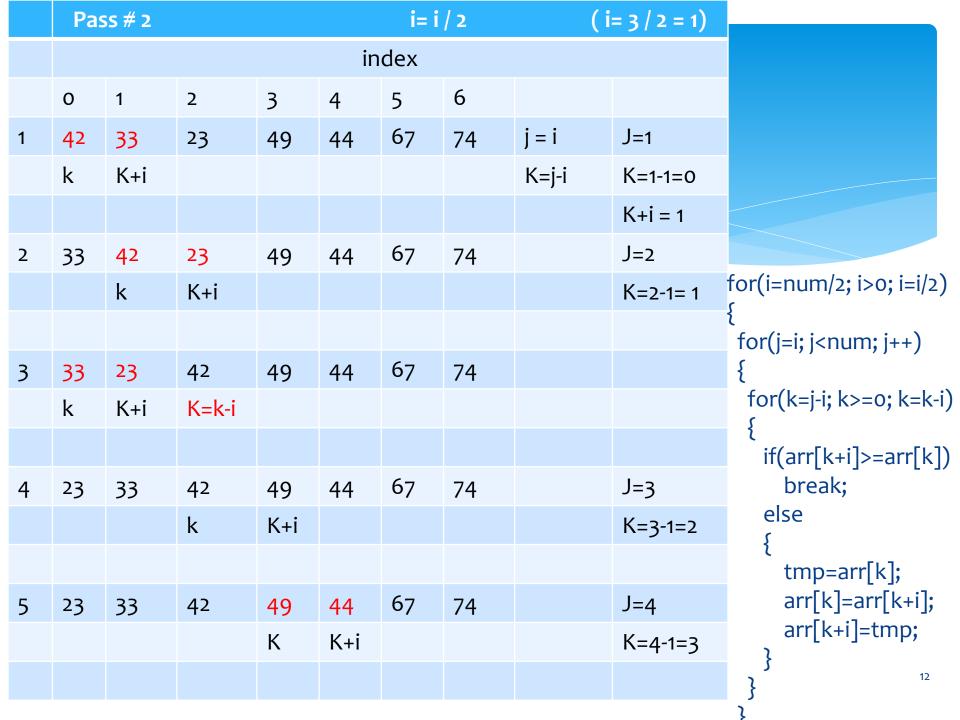

(a) Temp = A
$$[j]$$

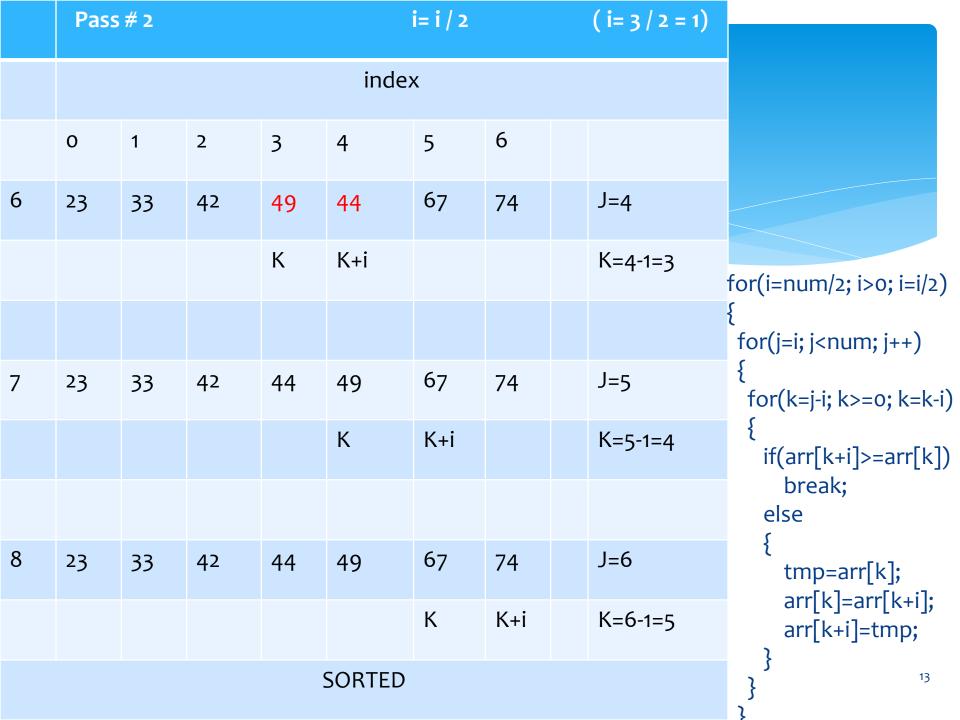

5. Initialise k = j-span and repeat through step 5 if (k > 0) and (temp < A [k])

$$(a) A [k + span] = A [k]$$

- 6. A [k + span] = temp
- 7. Exit

	Pa	SS # 1			i= nu	ım / 2		(i=)	7/2 = 3)	
					inde	X				
	0	1	2	3	4	5	6			
1	42	33	23	74	44	67	49	j = i	J=3	
	k			K+i				K=j-i	K=3-3=0	
									K+i = 3	
2	42	33	23	74	44	67	49		J=4	for(i=num/2; i>0; i=i/2)
		k			K+I				K=4-3=1	{ for(j=i; j <num; j++)<="" td=""></num;>
										{
3	42	33	23	74	44	67	49		J=5	for(k=j-i; k>=0; k=k-i) {
			k			K+i			K=5-3=2	if(arr[k+i]>=arr[k])
										break; else
4	42	33	23	74	44	67	49		J=6	{
				k	swap		K+i		K=6-3=3	tmp=arr[k]; arr[k]=arr[k+i];
	42	33	23	49	44	67	74			arr[k+i]=tmp;
										} }
										١

Shell sort: program

```
#include<stdio.h>
#include<conio.h>
int main()
int arr[30];
int i,j,k,tmp,num;
printf("Enter total no. of elements : ");
scanf("%d", &num);
for(k=0; k<num; k++)
  printf("\nEnter %d number : ",k+1);
  scanf("%d",&arr[k]);
for(i=num/2; i>0; i=i/2)
  for(j=i; j<num; j++)
   for(k=j-i; k>=0; k=k-i)
     if(arr[k+i] > = arr[k])
       break:
```

```
else
      tmp=arr[k];
      arr[k]=arr[k+i];
      arr[k+i]=tmp;
printf("For vlue of increment %d = \n\, i);
 for(j=0; j<num; j++)
  printf("%d\t",arr[j]);
  printf("\n\n");
printf("\t**** Shell Sorting ****\n");
for(k=0; k<num; k++)
  printf("%d\t",arr[k]);
getch();
return o;
```

Shell sort: complexity

- If an appropriate sequence of increments is classified, then the order of the shell sort is:
 - $f(n) = O(n (\log n))$

Shell sort: issues

- > Algorithm to be used to sort subsequences in shell sort
 - Straight insertion sort
 - Shell sort is better than the insertion sort
 - Lower number of passes than n number of passes in insertion sort
- Deciding the values of increments
 - Several choices have been made

Radix sort

- Radix sort or bucket sort is a method that can be used to sort a list of numbers by its base
- If we want to sort list of English words, where radix or base is 26, then 26 buckets are used to sort the words

Radix sort: example

Input: 478, 537, 9, 721, 3, 38, 123, 67

BucketSort on 1's

0	1	2	3	4	5	6	7	8	9
	721		03				5 <u>3</u> 7 <u>6</u> 7	478 38	ର

BucketSort on 10's

0	1	2	3	4	5	6	7	8	9
003 009		123	53 8			<u>0</u> 67	478		

BucketSort on 100's

0	1	2	3	4	5	6	7	8	9
3 9 38 67	123			478	537		721		

Output: 3,9,38,67,123,478,537,721

Radix sort: example (1st Pass)

Bucket sort by 1's digit

Input data

0	1	2	3	4	5	6	7	8	9
	721		3 12 <u>3</u>				537 6 <u>7</u>	478 3 <u>8</u>	9

After 1st pass

Radix sort: example (2nd Pass)

After 1st pass

Bucket sort by 10's digit

0	1	2	3	4	5	б	7	8	9
03 Q9		721 1 <u>2</u> 3	537 <u>3</u> 8			67	478		

After 2nd pass

Radix sort: example (3rd Pass)

After 2 nd pass					icket 100°						After 3 rd pass		
3 9				dig				3					
721	0	1	2	3	4	5	6	7	8	9	9 38 67		
123	003	123			478	537		721			67		
537	009										123		
537 38 67	038										478		
67	067										537		
478											721		

Invariant: after k passes the low order k digits are sorted.

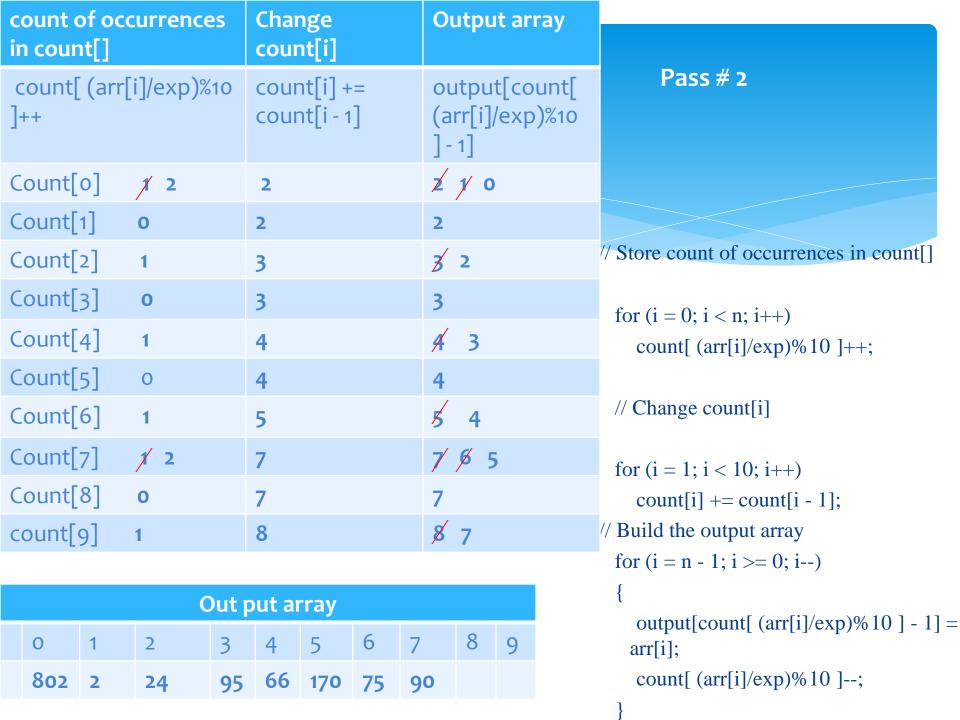

Radix sort: algorithm

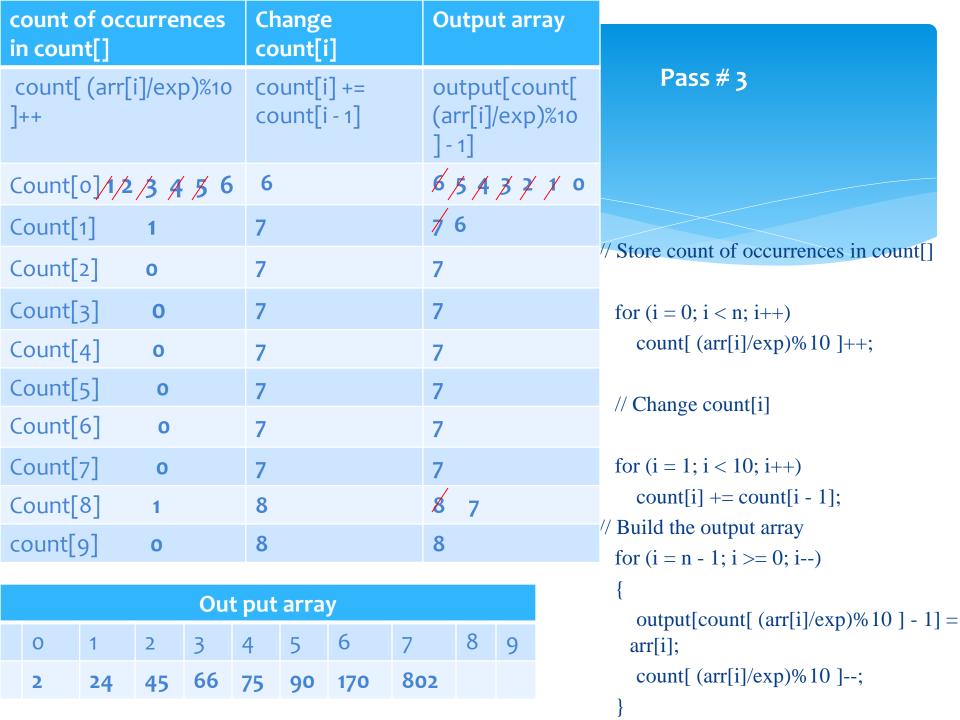

- Let A be a linear array of n elements A [1], A [2], A [3],..... A [n]. Digit is the total number of digits in the largest element in array A.
- 1. Input *n* number of elements in an array A.
- 2. Find the total number of Digits in the largest element in the array.
- 3. Initialize i = 1 and repeat the steps 4 and 5 until ($i \le Digit$).
- 4. Initialize the buckets j = 0 and repeat the steps (a) until (j < n)
 - (a) Compare *i*th position of each element of the array with bucket number and place it in the corresponding bucket.
- 5. Read the element(s) of the bucket from 0th bucket to 9th bucket and from first position to higher one to generate new array A.
- 6. Display the sorted array A.
- 7. Exit.

Radix sort: example

                                                                41.
                                                                       // Find the maximum number to know
31.
                                                                42.
                                                                            number of digits
32.
       // Copy the output array to arr[], so that arr[] now
                                                                43.
                                                                       int m = getMax(arr, n);
33.
       // contains sorted numbers according to current digit
                                                                44.
                                                                       // Do counting sort for every digit. Note
34.
       for (i = 0; i < n; i++)
                                                                45.
                                                                            that instead of passing digit
35.
         arr[i] = output[i];
                                                                46.
                                                                       // number, exp is passed. exp is 10<sup>i</sup> where
36. }
                                                                47.
                                                                            i is current digit number
                                                                       for (int \exp = 1; m/\exp > 0; \exp *= 10)
                                                                48.
                                                                49.
                                                                          countSort(arr, n, exp);
                                                        28
                                                                50.
```

Advantages and disadvantages

Advantages

- Radix and bucket sorts are stable, preserving existing order of equal keys
- They work in linear time, unlike most other sorts. In other words, they do not bog down when large numbers of items need to be sorted. Most sorts run in O(n log n) or O(n^2) time.
- The time to sort per item is constant, as no comparisons among items are made. With other sorts, the time to sort per time increases with the number of items.
- Radix sort is particularly efficient when you have large numbers of records to sort with short keys

Drawbacks

- Radix and bucket sorts do not work well when keys are very long, as the total sorting time is proportional to key length and to the number of items to sort
- They are not "in-place", using more working memory than a traditional sort

Radix sort: running time analysis

- ➤ How many passes?
- How much work per pass?
- ➤ Total time?
- Conclusion
 - Not truly linear if K is large
- In practice
 - Radix Sort only good for large number of items, relatively small keys
 - Hard on the cache, vs. MergeSort/QuickSort

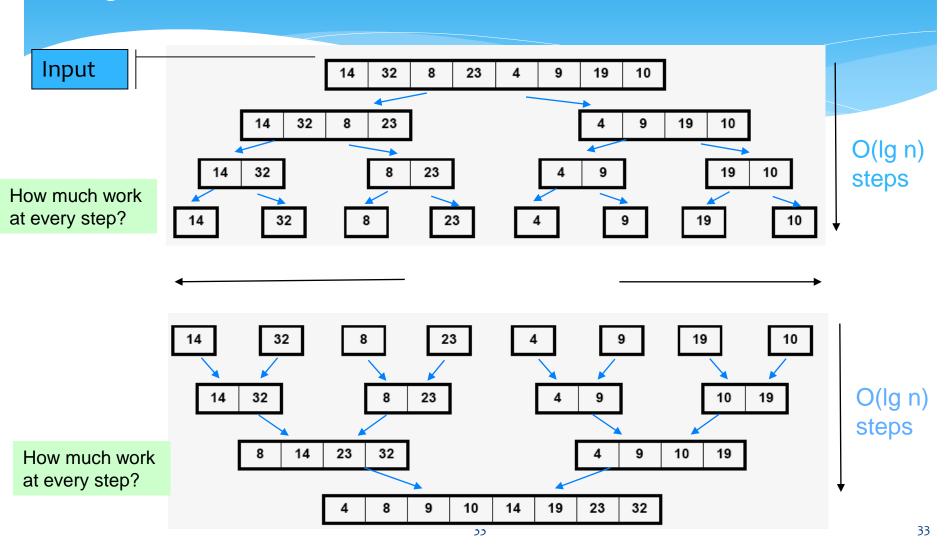

Radix sort: running time analysis

- Time requirement for the radix sorting method depends on the number of digits and the elements in the array
- > WORST CASE
 - $f(n) = O(n^2)$
- **BEST CASE**
 - $f(n) = O(n \log n)$
- > AVERAGE CASE
 - $f(n) = O(n \log n)$

Merge sort

- ➤ Merge sort is based on the **divide-and-conquer** paradigm
- Conceptually, a merge sort works as follows:
 - 1. Divide the unsorted list into *n* sub lists, each containing 1 element (a list of 1 element is considered sorted)
 - 2. Repeatedly merge sub lists to produce new sorted sub lists until there is only 1 sub list remaining. This will be the sorted list

Merge sort

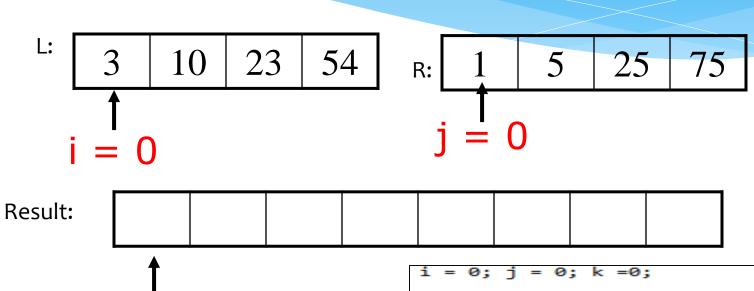

Merge sort

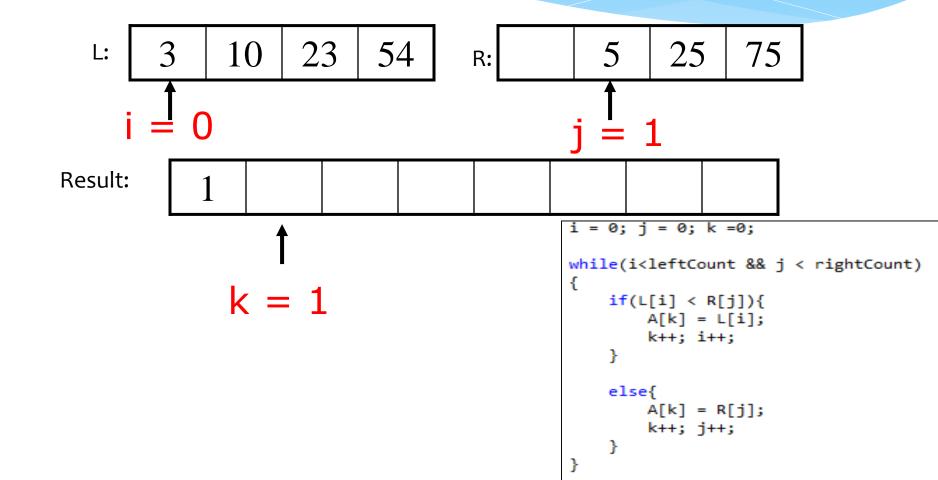

```
void MergeSort(int *A,int n) {
    int mid, i, *L, *R;
    if(n < 2)
        return; // base condition. If the array has less than two element, do nothing.
    mid = n/2; // find the mid index.
    // create left and right subarrays
    // mid elements (from index 0 till mid-1) should be part of left sub-array
    // and (n-mid) elements (from mid to n-1) will be part of right sub-array
    L = (int*)malloc(mid*sizeof(int));
    R = (int*)malloc((n - mid)*sizeof(int));
                                                               32
                                                                    23
                                                                            19
                                                       14
